

Ship your own

the whole day

Take what you have learned over the last two days and apply it to the project you want to build.

If you do not have a project, build me a wireless design tool that mimics Hamina. The brief is in `brief.md`.

The brief: build a wireless design tool that mimics Hamina

You've used Hamina. You know what a wireless design tool does from the user's side of the screen, which means you already have the requirements in your head. Build your own.

A full one does all of this:

- Loads a floor plan and sets its scale.
- Lets you draw walls and give each one an attenuation.
- Lets you place access points, name them, and set their band, channel and transmit power.
- Predicts coverage and draws it over the floor plan as a heat map.
- Works out a channel plan that keeps co-channel neighbours apart.
- Counts what the design needs: access points, by model.
- Saves the design and opens it again.
- Exports a report you could hand to a customer.

That is a product. The brief is too big on purpose: you are building one piece of this tool.

You pick the piece. Start from the one you'd use yourself, or the one you've always thought the real tools get wrong.

Your version doesn't have to match this page. If the list sparks a different idea, build that.
